# INTRODUCTION

In this chapter we introduce key concepts that will be used in later chapters. For this reason, unlike other chapters it contains many statements, sometimes given without thorough explanations or reasoning. While all of these statements are grounded in deep ideas and can be formulated in a rigorous manner, it is advised to first get an intuitive understanding of the ideas before diving into their more formal construction.

## **Note 0.1 In case you are already familiar with the topics**

It is recommended for readers who are familiar with the topics to at least gloss over this chapter and make sure they know and understand all the concepts presented here.

## 1.1 SEQUENCES AND SERIES

---

### 1.1.1 Basics

A **sequence** is an indexed collection of **elements**. By *indexed* we mean that the order of the elements in a sequence matters (unlike with sets): changing the order of any element changes the sequence as a whole. The following are some examples of sequences composed of real numbers:

- $1, -3, 0, -7, 2, 1.5, 4, 0, 1, -0.35, \sqrt{2}$ .
- $0, 1, 2, 1, 1, -1, 0$ .
- $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}, \dots$

- 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, ...

The examples above present two more properties of sequences:

- Elements may repeat (unlike in the case of sets), and
- sequences can be either **finite** (as in the first two examples), or **infinite** (as in the latter two examples).

The number of elements in a sequence is called its **length**. In the case of infinite sequences we say that their length equals  $\infty$  (infinity). The elements of a sequence  $a$  are usually indexed using a subscript, such that  $a_1$  is the first element in the sequence,  $a_2$  is the second element in the sequence, etc. - and generally  $a_i$  is the  $i$ -th element in the sequence, where  $i \in \mathbb{N}$ .

We can therefore define a sequence somewhat more formally as a function from a subset of the natural numbers to the real numbers:

$$a : N \rightarrow \mathbb{R}, \quad (1.1.1)$$

where  $N \subseteq \mathbb{N}$ .

### Example 1.1 Sequences as functions

The following 9-element sequence  $a$

$$\begin{array}{cccccccccc} 3, & 4, & \frac{1}{2}, & 0, & 2, & 6, & -\frac{2}{3}, & 0, & -1. \\ \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow \\ a(1) & a(2) & a(3) & a(4) & a(5) & a(6) & a(7) & a(8) & a(9) \end{array}$$

can be viewed as a function

$$a : \{1, 2, \dots, 9\} \rightarrow \mathbb{R},$$

or more precisely as a function

$$a : \{1, 2, \dots, 9\} \rightarrow \left\{ -1, -\frac{2}{3}, 0, \frac{1}{2}, 2, 3, 4, 6 \right\}.$$

The follow infinite sequence  $b$

$$\begin{array}{ccccccc} 1, & \frac{1}{2}, & \frac{1}{3}, & \frac{1}{4}, & \frac{1}{5}, & \frac{1}{6}, & \frac{1}{7}, & \dots \\ \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \\ b(1) & b(2) & b(3) & b(4) & b(5) & b(6) & b(7) & \end{array}$$

can be viewed as a function

$$b : \mathbb{N} \rightarrow (0, 1].$$

Since sequences can be viewed as functions, they can be defined using formulas: for example, the sequence

$$1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \dots$$

can be defined using the simple formula

$$a_n = \frac{1}{n}.$$

### Example 1.2 Some sequences defined using formulas

$$(-1)^n \Rightarrow -1, 1, -1, 1, -1, 1, -1, 1, -1, \dots$$

$$3n + 4 \Rightarrow 7, 10, 13, 16, 19, 22, \dots$$

$$(n+1)^2 \Rightarrow 4, 9, 16, 25, 36, 49, \dots$$

$$\begin{cases} 2n+1 & \text{if } n \text{ is odd,} \\ n-1 & \text{if } n \text{ is even.} \end{cases} \Rightarrow 3, 1, 7, 3, 11, 5, 15, 7, \dots$$

Sequences can also be defined using **recursion**, where the value of an element is defined using previous values and a **starting value**. For example:

$$a_n = a_{n-1}^2 - 2,$$

with the starting value  $a_1 = 3$ . We then get that

$$a_2 = a_1^2 - 2 = 3^2 - 2 = 7,$$

and thus

$$a_3 = a_2^2 - 2 = 7^2 - 2 = 47,$$

etc.

### Example 1.3 The Fibonacci sequence

The **Fibonacci sequences** is a well-known sequence defined using the following recursive rule:

$$F_n = F_{n-1} + F_{n-2},$$

with  $F_1 = F_2 = 1$ . The first few elements of the sequence are therefore

$$1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, \dots$$

See [Figure 1.1](#) for a graphical representation of the Fibonacci sequence.

**Figure 1.1** A graphical representation of the Fibonacci sequence: two squares of side 1 are placed adjacent to each other on the plane. In each subsequent step a new square is placed such that its side is equal to the combined sides of the previous two squares. This way, the side of each square in the sequence follows the Fibonacci sequence. In each square we draw a quarter circle centered on one of the vertices, such that we get the famous **golden ratio** helix.

**Note 1.1 Focus of section**

From now on in the section we will focus on infinite sequences only.

**1.1.2 Types of sequences**

Consider the sequence  $a_n = n^2$ . Since  $n \in \mathbb{N}$ , for any  $n$ ,  $a_{n+1} > a_n$ , since  $(n+1)^2 > n^2$  (see Figure 1.2). We say that such a sequence is **increasing**. In fact, for a sequence to be increasing some sequential elements can be equal: for example, the sequence  $c_n = 1, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4, 5, 5, \dots$  is also an increasing sequence. Thus, the definition of an increasing sequence is the following:

**Definition 1.1 increasing sequence**

sequence  $a_n$  is said to be *increasing* if for any  $n \in \mathbb{N}$ ,  $a_{n+1} \geq a_n$ .

If we change the condition to  $a_{n+1} > a_n$  we say that such a sequence is **strictly increasing**. In the above examples  $a_n$  is a strictly increasing sequence, while  $c_n$  is just increasing (since for some indices  $n$ ,  $c_{n+1} = c_n$ ).

Similarly, a **decreasing** sequence is a sequence  $b_n$  for which for any  $n \in \mathbb{N}$ ,  $b_{n+1} \leq b_n$ . An example of such sequence is  $b_n = \frac{1}{n}$  (see Figure 1.3). And of course, if we change the condition to  $b_{n+1} < b_n$  then the sequence is **strictly decreasing**.

Generally, a sequence that is either increasing or decreasing is said to be **monotone**. If a sequence is monotone starting only from a certain  $n$ , we say that the sequence is **eventually monotone** (i.e. *eventually increasing* or *eventually decreasing*). An example of such sequence is  $d_n = (n-5)^2$  (Figure 1.4): for  $N \in 1, 2, 3, 4, 5$  it is decreasing, but starting from  $n = 5$  it is increasing for any  $n$ .

As an example of a sequence which isn't monotone, consider the sequence  $e_n = \sin(n)$ : for some values of  $n$ ,  $e_{n+1} > e_n$  and for some other values  $e_{n+1} < e_n$  (see Figure 1.6).

The following are two ways to determine whether a sequence  $a_n$  is monotone:

- **Difference test:** if  $a_{n+1} - a_n \geq 0$  for all  $n \in \mathbb{N}$ , then the sequence is increasing. If  $a_{n+1} - a_n \leq 0$  for all  $n \in \mathbb{N}$  then the sequence is decreasing.
- **Ratio test:** if  $\frac{a_{n+1}}{a_n} \geq 1$  for all  $n \in \mathbb{N}$  then the sequence is increasing, and if  $\frac{a_{n+1}}{a_n} < 1$  for all  $n \in \mathbb{N}$  then the sequence is decreasing.

**Example 1.4 Difference test**

Given the sequence  $a_n = \frac{n}{n+1}$ , we look at the difference  $a_{n+1} - a_n$ :

$$a_{n+1} - a_n = \frac{n+1}{n+2} - \frac{n}{n+1} = \frac{(n+1)(n+1) - (n+2)n}{(n+1)(n+2)}$$

Figure 1.2 The sequence  $a_n = n^2$  is increasing, and is in fact *strictly* increasing.

Figure 1.3 The sequence  $b_n = \frac{1}{n}$  is decreasing, and is in fact *strictly* decreasing.

**Figure 1.4** The sequence  $d_n = (n-5)^2$  starts as a decreasing sequence, but starting from  $n = 5$  it is increasing, making it an *eventually increasing sequence*.

**Figure 1.5** The sequence  $e_n = \sin(n)$  is neither increasing nor decreasing. For reference, the function  $\sin(x)$  is plotted as a dashed line behind  $e_n$ .

$$= \frac{n^2 + 2n + 1 - n^2 - 2n}{(n+1)(n+2)} = \frac{1}{(n+1)(n+2)} < 1 \quad \forall n \in \mathbb{N}.$$

The last (in)equality stems from the fact that no matter what  $n$  we substitute into  $(n+1)(n+2)$ , the result will be greater than 1, and thus  $\frac{1}{(n+1)(n+2)}$  is always smaller than 1. Therefore,  $a_n$  is a decreasing sequence.

### Example 1.5 Ratio test

Given the sequence  $b_n = \frac{2^n}{n^2}$ , the ratio of  $a_{n+1}$  to  $a_n$  is

$$\frac{a_{n+1}}{a_n} = \frac{\frac{2^{n+1}}{(n+1)^2}}{\frac{2^n}{n^2}} = 2 \frac{n^2}{(n+1)^2}.$$

Let's look at the first few approximated values of the ratio  $\frac{n^2}{(n+1)^2}$ :

$n$	$\frac{n^2}{(n+1)^2}$
0	0
1	0.25
2	0.44444...
3	0.5625
4	0.64
5	0.69444...
6	0.7346938775510204
7	0.765625
8	0.7901234567901234
9	0.81
10	0.8264462809917356
11	0.840277777...
12	0.8520710059171598
13	0.8622448979591837

We see that for any  $n \geq 3$ ,  $\frac{n^2}{(n+1)^2} > \frac{1}{2}$ , and therefore  $2 \frac{n^2}{(n+1)^2} > 1$ . Thus, the sequence is eventually increasing.

Some sequences are **bounded** from below: this means that their elements never get

smaller than some constant  $\underline{M} \in \mathbb{R}$ . For example, consider the simple sequence  $a_n = n$ , where  $n = \{1, 2, 3, 4, \dots\}$ : there is no element in the sequence that is smaller than 1. Therefore,  $a_n$  is bounded from below by 1. Of course, one may argue that  $b_n$  is also bounded from below by 0, or  $-6$ , or in fact any negative number. This is true, however we are usually interested in the *maximal* number  $\underline{M}$  that bounds the sequence from below, which in this case is  $\underline{M} = 1$ . We call that number the **infimum** of the sequence, and denote it as  $\inf a_n$ .

Similarly, a sequence  $a_n$  can be bounded from above by some number  $\overline{M} \in \mathbb{R}$ , i.e. there exist no  $n$  for which  $a_n > \overline{M}$ . We call the *minimal* such number the **supremum** of the sequence  $a_n$ , denoted  $\sup a_n$ . For example, the sequence  $b_n = \frac{1}{n}$  is bounded from above by any real number  $x \geq 1$ , and therefore  $\sup b_n = 1$ . In fact,  $b_n$  is also bounded from below by  $\underline{M} = 0$ , and therefore we say that it is **bounded**. Another example of a sequence that is bounded is  $e_n = \sin(n)$ , which is bounded from below by  $\underline{M} = -1$  and from above by  $\overline{M} = 1$ .

### Example 1.6 Bounded and unbounded sequences

The following table shows some examples of sequences that are bounded from below, from above, or neither:

$a_n$	First 5 elements	$\inf a_n$	$\sup a_n$
$n^2 - n$	0, 2, 6, 12, 20, ...	0	-
$\frac{n}{n+1}$	$\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \dots$	$\frac{1}{2}$	1
$e^{-n}$	$e^{-1}, e^{-2}, e^{-3}, e^{-4}, e^{-5}, \dots$	0	$e^{-1}$
$\log(n)$	0, $\log(2)$ , $\log(3)$ , $\log(4)$ , $\log(5)$ , ...	0	-
$(-1)^n$	-1, 1, -1, 1, -1, ...	-1	1
$(-1)^n n$	-1, 2, -3, 4, -5, ...	-	-
$(-2)^n$	-2, 4, -8, 16, -32, ...	-	-

### 1.1.3 Subsequences

Given any sequence  $a_n$ , we can remove from it any number of its elements (including 0 elements) and get a new sequence  $b_n$  which is a **subsequence** of  $a_n$ . For example, let  $a_n = n^2 - 5n$ . We can remove each 2nd element from  $a_n$  (i.e. those with indices 2, 4, 6, 8, ...) and get the following sequence  $b_n$ :

**Note 1.2 Order of elements in a subsequence**

A subsequence must preserve the order of the original sequence, since all we do in practice is removing elements from the original sequence, without changing the order of the remaining elements.

Let's look at a more formal definition of a subsequence, which uses the choice of indices instead of removing elements:

**Definition 1.2 Subsequence**

A subsequence of a sequence  $a_n$  is a sequence  $a_{n_k}$ , where  $n_k$  is a **strictly increasing** sequence of natural numbers.

To create a subsequence using the above definition, one can first create a sequence of indices  $n_k$ , and then substitute only those indices into  $n$  in  $a_n$ . For example, given the sequence  $a_n = n^2 - 5n$  from before, we can define a sequence of indices  $n_k = 1, 3, 5, 7, 9, 11, \dots$  which would then yield the subsequence  $b_n$  shown before.

The reason we define  $n_k$  to be strictly increasing is to avoid changing the order of the elements from the original sequence  $a_n$ : for example, if we allowed  $n_k$  to be "just" increasing, we might end up with a case where there are two subsequent equal indices, e.g.  $n_k = 1, 3, 5, 8, 9, 9, 10, \dots$ . That would mean that we repeat an element from  $a_n$  **twice or more** in the subsequence (in the example this would be  $a_9$ ), rendering it invalid as a subsequence, since as mentioned before - a subsequence must preserve the order of the original sequence.

Subsequences share all of the above-mentioned properties of the original sequence: if the original sequence is increasing or decreasing - so do all of its subsequences, and if it is bounded from above or below - so do all of its subsequences. Let's prove two of these properties:

**Proof 1.1 Rising sequences and their subsequences**

**Claim:** given an **increasing** sequence  $a_n$ , all of its subsequences are also increasing sequences themselves.

**Proof:** using contradiction. Let  $a_n$  be an increasing sequence, and  $b_n$  a subsequence of  $a_n$  which isn't increasing. From the fact that  $b_n$  is not an increasing sequence we know that there exist at least two indices  $k, m$  such that  $k < m$  but  $b_k > b_m$ . Since any  $b_n$  is an element of  $a_n$  without change of order, we can substitute  $b_k = a_i$  for some index  $i$  and  $b_m = a_j$  for some index  $j$ , such that  $i < j$  (since  $k < m$  - this is exactly the idea of preserving the order of  $a_n$ ). We therefore get that  $a_i = b_k > b_m = a_j$ , or simply  $a_i > a_j$  even though  $i < j$  - in contradiction to  $a_n$  being an increasing sequence. Therefore there can be no subsequence of  $a_n$  that isn't an increasing sequence.

**QED**

**Proof 1.2 Bounded sequences and their subsequences**

**Claim:** given a sequence  $a_n$  which is **bounded from below**, all of its subsequences are also bounded from below.

**Proof:** also using contradiction. Let  $a_n$  be a sequence bounded from below by  $\inf a_n = \underline{M}$ . Let  $b_n$  be a subsequence of  $a_n$  that isn't bounded from below - i.e. there exist an element  $b_i$  such that  $b_i < \underline{M}$ . Since  $b_n$  is a subsequence of  $a_n$ ,  $b_i = a_j$  for some index  $j$ . Therefore  $a_j = b_i < \underline{M}$  in contradiction to  $\underline{M}$  being the infimum of  $a_n$ . Therefore, a subsequence of a sequence bounded from below can not be unbounded from below.

**QED****Challenge 1.1 Further proofs**

- 1.1. Prove that all subsequences of a decreasing sequence are themselves decreasing.
- 1.2. Prove that all subsequences of a sequence bounded from above are themselves bounded from above.
- 1.3. Prove that all subsequences of a **strictly** increasing/decreasing sequence are themselves increasing or decreasing, respectively.
- 1.4. Given a bounded sequence  $a_n$  with  $\inf a_n = \underline{M}$ , can it have a subsequence  $b_n$  with  $\inf b_n \neq \underline{M}$ ? If yes - give an example. If no - prove your claim.

?

**1.1.4 Convergence**

As you probably noticed by now, some infinite sequences seem to approach a certain value as we increase  $n$ . That is to say, the bigger  $n$  is, the closer such a sequence  $a_n$  gets to a certain value  $L \in \mathbb{R}$ . For example, the sequence  $b_n = \frac{1}{n}$  approaches to  $L = 0$  as we increase  $n$  (see again [Figure 1.3](#)). The sequence  $a_n = \frac{1}{n^2+1}$  approaches the value  $L = 0$  as we increase  $n$  (see ??). On the contrary, the sequence  $d_n = (n-5)^2$  eventually increase in such a way that it “approaches”  $L = \infty$ , while  $e_n = \sin(n)$  doesn't approach any value and instead endlessly “jumps” around in a repeated manner.

The formal term for the behaviour of  $a_n$  and  $b_n$  is called **convergence**, and it is one of the most important properties of infinite sequences. In this subsection we will define, analyze, and explain it in detail. To begin, we can divide all infinite sequences into three separate types:

- Sequences which do not converge into any value (e.g.  $\sin(n)$ ,  $\cos(n)$ , etc.).
- Sequences that “go to” positive or negative infinity (sometimes said to be “exploding”).
- Sequences which converge to a finite number  $L \in \mathbb{R}$ .

**Figure 1.6** The sequence  $a_n = \frac{1}{n^2} + 1$  approaches the value  $L = 1$  as  $n$  increases.

Let us start with a more precise analysis of the second type: sequences that “explode” to either positive or negative infinity. In essence, a sequence which goes to positive infinity is one which has a lower boundary  $\underline{M}$  but not upper boundary  $\overline{M}$ , that is - given any real number  $R$  the sequence eventually passes it, or more precisely: all the elements after a certain point are greater than  $R$ .

Take for example the sequence  $a_n = n^2$ . It most certainly has a lower bound, specifically  $\inf a_n = 1$ . On the other hand, given any  $R \in \mathbb{R}$  eventually the values of  $a_n$  pass it. For example, given  $R = 100$ , the elements of  $a_n$  pass it after just 10 elements (since  $a_{11} = 11^2 = 121 > 100$ ). The number  $R = 1,000,000$  is passed after 1000 elements, etc. No matter how big  $R$  is, **eventually**  $a_n$  will pass it. Therefore, we say that  $a_n$  “goes to” infinity, and denote the fact by writing

$$\lim_{n \rightarrow \infty} a_n = \infty. \quad (1.1.2)$$

(read: *the limit of  $a_n$  as  $n$  goes to infinity equals infinity*)

### Note 1.3 Another limit notation

Another common notation used to denote that a sequence  $a_n$  is going to infinity as  $n$  increases is the following:

$$a_n \xrightarrow{n \rightarrow \infty} \infty.$$

A more formal definition of this behaviour is as follows:

### Definition 1.3 Sequence going to infinity

Let  $a_n$  be an infinite sequence. If for any  $R \in \mathbb{R}$  there exist  $n_R \in \mathbb{N}$  such that for any  $n > n_R$ ,  $a_n > R$ , the sequence is said to be going to positive infinity. We denote

**Figure 1.7** The sequence  $a_n = \frac{n}{2}$  goes to positive infinity as  $n$  increases.

this fact by writing

$$\lim_{n \rightarrow \infty} a_n = \infty.$$

$\pi$

Of course, for negative infinity the behaviour is very similar: a sequence  $a_n$  with an upper boundary  $\overline{M}$  and no lower bound  $\underline{M}$  is said to be **going to negative infinity**, since for any  $R \in \mathbb{R}$  there exist an  $n_R \in \mathbb{N}$  for which if  $n > n_R$  then  $a_n < R$ .

Generally speaking, proving that a sequence goes to either positive or negative infinity follows a certain pattern, which we will exemplify using the sequence  $a_n = \frac{n}{2}$  (Figure 1.7). It should be clear that the sequence goes to positive infinity as  $n$  increases, since we can make the values of  $a_n$  as large as we want by substituting a respective  $n$  into  $\frac{n}{2}$ : for example, given  $R = 1000$  we can substitute  $n = 2000$ , yielding  $a_{2000} = \frac{2000}{2} = 1000$ , and thus any  $a_n$  where  $n > 2000$  will be bigger than  $R = 1000$ . For  $R = 1,000,000$  we can substitute  $n = 2,000,000$  and so forth.

To show that this is true for any  $R \in \mathbb{R}$  we should do the following: given a real number  $R$  find an index  $n_0$  such that  $a_{n_0} \geq R$ . Since  $a_n$  is a strictly increasing sequence, that would mean that for any  $n > n_0$ ,  $a_n > a_{n_0} \geq R$ , or simply  $a_n > R$ . In the case of  $a_n = \frac{n}{2}$  we can simply choose the closest integer to  $R$  that is also bigger than  $R$  (i.e. if  $R = 2.3$  we choose  $n_0 = 3$ , if  $R = 100.7$  we choose  $n_0 = 101$ , etc.). We can use the **ceiling** operator, which does exactly this: for any given  $x \in \mathbb{R}$ , its ceiling (denoted  $\lceil x \rceil$ ) is the closest integer which is bigger than or equal to  $x$ , or more formally:

#### Definition 1.4 Ceiling and floor operators

Let  $x \in \mathbb{R}$ . Then

$$\lceil x \rceil = \min \left( \{n \in \mathbb{N} \mid n \geq x\} \right). \quad (1.1.3)$$

$$\lceil x \rceil = \max\left(\{n \in \mathbb{N} \mid n \leq x\}\right). \quad (1.1.4)$$

i.e.  $\lceil x \rceil$  is the **minimal** integer  $n$  that is **bigger than or equal** to  $x$ , and  $\lfloor x \rfloor$  is the **maximal** integer  $n$  that is **smaller than or equal** to  $x$ .

$\pi$

Now that we have
